# Conditions and Logic I

## Warm-up

Last class, we looked at sequences. Test your knowledge by answering the following questions:

## **Questions (10 min)**

#### **Start time:**

1. Evaluate each expressions in order and write down what it evaluates to. If an error occurs, write what type of error. Place an asterisk (\*) next to any output for which you are unsure.

Python code	Output
seq1 = "one two"	
type(seq1)	
len(seq1)	
seq1[3] = ','	
seq1.replace(' ',',')	
<pre>print(seq1)</pre>	
seq2 = ["one", "two"]	
type(seq2)	
seq2[1] = 1	
print(seq2)	
seq2.append(1)	
print(seq2)	
seq2.count(1)	
seq3 = 'abcdefg'	
seq3[:]	
seq3[::-1]	
seq3[:-3]	
seq3[:-3:-1]	
seq3[-3:]	
seq3[-3:]	

2. What are similarities between lists and strings?

Computer programs make decisions based on logic: if some condition applies, do something, otherwise, do something else.

# **Model 1** Comparison Operators

In Python, a comparison (e.g., 100 < 200) will yield a *Boolean* value of either True or False. Most data types (including int, float, str and list) can be compared using the following operators:

Operator	Meaning	
<	less than	
<=	less than or equal	
>	greater than	
>=	greater than or equal	
==	equal	
!=	not equal	

Evaluate each expression in order and record the output for each line (if any) in the second column.

Python code	Output
type(True)	
type(true)	
type(3 < 4)	
print(3 < 4)	
three = 3	
four = 4	
<pre>print(three == four)</pre>	
check = three > four	
print(check)	
type(check)	
<pre>print(three = four)</pre>	
three = four	
<pre>print(three == four)</pre>	
three in range(0,17,4)	

- 3. What is the name of the data type for Boolean values?
- **4**. Do the words True and False need to be capitalized? Explain how you know.

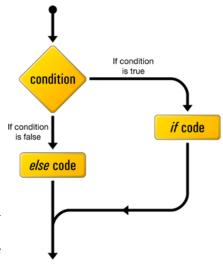

- 5. For each of the following terms, identify examples from the table:
  - a) Boolean variables:
  - b) Boolean operators:
  - c) Boolean expressions:
- **6**. Explain why the same expression three == four had two different results.
- 7. What is the difference between the = operator and the == operator?
- 8. Write a Boolean expression that uses the != operator and evaluates to False.

#### Model 2 if/else Statements

An **if** statement makes it possible to control what code will be executed in a program, based on a condition. For example:

```
def main() -> None:
number = int(input("Enter an integer: "))
if number < 0:
    print(number, "is negative")
else:
    print(number, "is a fine number")
print("Until next time...")</pre>
```

Python uses *indentation* to define the structure of programs. The line indented under the <u>if</u> statement is executed only when number < 0 is <u>True</u>. Likewise, the line indented under the <u>else</u> statement is executed only when number < 0 is <u>False</u>. The flowchart on the right illustrates this behavior.

**9**. What is the Boolean expression in the code snippet above?

<b>10</b> . What is the output when the user enters the number 5? What is the output when the user enters the number -5? <b>STOP HERE</b> The instructor will trace the code with you using the debugger.
<b>11</b> . After an if-condition, what syntax differentiates between (1) statements that are executed based on the condition and (2) statements that are always executed?
<b>12</b> . What happens if you indent code inconsistently? For example, what would happen if you enteredprint("Hello") into a Python Editor (where _ is a space), save the file as hello.py, and run the program?
<b>13</b> . Based on the program above, what must each line preceding an indented block of code end with?
14. Write an if statement that first determines whether number is even or odd, and then prints the message "(number) is even" or "(number) is odd". (Hint: use the % operator.)
<b>15</b> . Does an <b>if</b> statement always need to be followed by an <b>else</b> statement? Why or why not? Give an example.
Model 3 Boolean Operations
Expressions may include Boolean operators to implement basic logic. If all three operators appear in the same expression, Python will evaluate not first, then and, and finally or. If there

are multiple of the same operator, they are evaluated from left to right. Evaluate the following expressions based on the variables a = 3, b = 4, and c = 5:

Python code	Output
<pre>print(a &lt; b and b &lt; c)</pre>	
<pre>print(a &lt; b or b &lt; c)</pre>	
<pre>print(a &lt; b and b &gt; c)</pre>	
<pre>print(a &lt; b or b &gt; c)</pre>	
<pre>print(not a &lt; b)</pre>	
<pre>print(a &gt; b or not a &gt; c and b &gt; c)</pre>	
<pre>print(a not in [a,b,c])</pre>	
<pre>print(a not in ['a',b,c])</pre>	
<pre>print(a not in 'abc')</pre>	
print(a not in 345)	

- 16. What data type is the result of a < b? What data type is the result of a < b and b < c?
- 17. What is the value of a < b? What is the value of b < c?
- **18**. If two True Boolean expressions are combined using the and operator, what is the resulting Boolean value?
- 19. Write an expression that will combine two False Boolean expressions using the or operator.
- **20**. Assuming P and Q each represent a Boolean expression that evaluates to the Boolean value indicated, complete the following table. Compare your team's answers with another team's, and resolve any inconsistencies.

Р	Q	P and Q	P or Q
False	False		
False	True		
True	False		
True	True		

- 21. Assume that two Boolean expressions are combined using the and operator. If the value of the first expression is False, is it necessary to determine the value of the second expression? Explain why or why not.
- **22**. Assume that two Boolean expressions are combined using the **or** operator. If the value of the first expression is **True**, is it necessary to determine the value of the second expression? Explain why or why not.
- **23**. Examine the last row of the table. Evaluate the Boolean expression following the order of precedence rules. Show your work by rewriting the line at each step and replacing portions with either True or False.

a > b or not a > c and b > c

- **24**. Suppose you wanted to execute the statement sum = x + y only when both x and y are positive. Determine the appropriate operators, and write a single Boolean expression for the if-condition.
- **25**. Rewrite the expression from #24 using the **not** operator. Your answer should yield the same result as in #24, not the opposite. Describe in words what the new expression means.
- **26**. Suppose that your team needs to execute the statement sum = x + y except when both x and y are positive. Write a Boolean expression for this condition. How is it different from the previous question?
